16. Abstract The UMTA sponsored Urban Rail Supporting Technology Program emphasizes three major task areas; facilities development, technology development, and test program development. The test program development is composed of three sub-areas; vehicle testing, ways and structures testing, and track geometry measurement. This report, in five volumes, presents the technical methodology, data samples, and results of tests conducted on the Massachusetts Bay Transit Authority (MBTA) Green Line in December, 1972 prior to initiation of the Green Line refurbishment effort.  An instrumented revenue type car was used for the measurement of track geometry, ride roughness, and interior noise. Actual car speed was approximately the same as normal revenue speed. The objectives of the tests were to identify critical track sections for improvement to quantify the benefits produced by the track rehabilitation program, and to provide data for TSC's development of an advanced track geometry measurement system.  Volume IV presents the track profile computer printout for the Westbound Track.			
17. Key Words Track measurement methods, Track geometry measurement, Ride roughness measurement, Interior noise measurement		18. Distribution Statement  DOCUMENT IS AVAILABLE TO THE PUBLIC THROUGH THE NATIONAL TECHNICAL INFORMATION SERVICE, SPRINGFIELD, VIRGINIA 22151.

## VOLUME IV WESTBOUND TRACK PROFILE COMPUTER PRINTOUT

This Volume contains the Westbound (Lechmere to Riverside) track profile computer printout for the MBTA Green Line (Riverside Line) tests run in December, 1972. Examples of this data were presented in Volume I of this report.

A map of the Green Line is shown in Figure 1, and station distances are given in Figure 2.

As an aid to the reader, the Summary Sheet and the Test and Data Sections of Volume I, Appendix B, are reprinted here.

MBTA Green Line Tests, Riverside Branch

December, 1972

SEQUENCE NO.      12-72-601

PROCEDURE NO.    PCC-TGC-6007-MBTA

OBJECTIVE:

To measure midchord track profile on the Riverside Branch of the Green Line, prior to initiation of track rehabilitation. These data will help establish which sections of track most severely require rework. These data will also be used for comparison with data recorded after the track has been ungraded.

STATUS:

Midchord profile data (10 foot chord) has been collected and processed for the twenty six-plus miles of the Riverside Branch track. The data is presented in 46 sets with each set representing a one-way section of track between two adjacent stations.

### Test Description

In this test series, midchord profile of each rail is measured continuously using capacitive proximity detectors. Three probes are mounted on straight beams that are located alongside the wheels of the instrumented truck. Each probe is centered over the top surface of the rail. The electronics associated with each probe puts out a voltage that is proportional to the distance between the probe and the rail. Thus, if the outputs of the two end probes are denoted A and B and the output of the center probe is denoted C, the mid-chord formula yields the midchord offset h as

$$h = \frac{A + B}{2} - C$$

(see Figure 3). The midchord offset is the actual output of this measurement. The beam length used in this test series was 9 ft. 10 in.

Figure 3 Measurement of Midchord Offset

## Data

The midchord profile data were recorded on analog tape during the test runs in the form of the outputs of each of the capacitance probe circuits as well as the computed midchord value. The data was then digitized after passing it through a Butterworth low-pass, four-pole, filter set for 30 Hz, and a unity gain amplifier. The tachometer pulses were divided down by a factor of 7810 and used to trigger the sampling of the Analog-to-Digital Converter.

A total of 23 sets of printout pages, corresponding to the 23 intervals between stations on the Westbound trip between Lechmere and Riverside, are contained in this volume.

Left and right midchord profiles are shown on separate sets of printouts for the 10-foot beam. Vehicle speed was intended to approximate typical revenue speed.

The sampled data were processed to locate the largest profile perturbations. The magnitude of the profile was divided according to zones of perturbation. The nominal zone with  $\pm 0.25$  inches midchord is defined as zone zero. Positive mid-chord measurements greater than 0.25 inches are defined by even numbered zones (e.g., 2 and 4). Negative midchord measurements less than 0.25 inches are defined by odd numbered zones. The size at the zones used here are defined as follows:

<u>Zone</u>	<u>Mid-chord Reading</u>
4	0.75 in. $\leq P$
2	+0.25 in. $\leq P < +0.75$ in.
0	-0.25 in. $< P < +0.25$ in.
1	-0.75 in. $< P \leq -0.25$ in.
3	$P \leq -0.75$ in.

The complete profile printout data, pages A, B and C for the 46 sections of track are given in Volume III and IV of this report. This volume gives the printouts for the 23 sections of the Westbound track, and Volume III gives them for the 23 related sections of the Eastbound track. Pages A on the printout charts show the location each time the profile reading enters a new zone. Pages B on the printout summarize the locations at which the peaks are reached in the extreme zones, 3 and 4. The magnitude of the peak is also given. Pages C on the printout summarize the section of track in terms of number of times each zone occurs and total number of feet in each zone.

The summary page, C, if each group can be used for comparison of one section of track with another. Pages B, by giving the location of the most severe perturbations, can be used for locating areas for investigation and possible repairs.
